A comparative study of copper supplementation in childbearing women with various dietary habits. The purpose of this study was to elucidate the effect of copper supplementation on pregnant women with various dietary habits. Cu, iron and Zn levels in serum, hemoglobin (Hb), HbA1c, and bone mineral density were measured. One hundred pregnant women were divided into three groups according to their dietary habits. The first group comprised 20 women with good dietary habits (G), the second group included 30 women with unsatisfactory dietary habits (S), and the third group comprised 50 women with borderline dietary habits (B). Mean values of serum Cu levels in G, S, and B were 50.9 +/- 8.9, 44.4 +/- 7.5, and 42.8 +/- 5.7 micrograms/dl, respectively, and those of serum Zn levels were 57.0 +/- 9.6, 58.3 +/- 9.0, and 54.7 +/- 7.9 micrograms/dl, respectively. There were no significant differences in the serum Cu levels of the three groups, and serum Zn levels were significantly lower in the B group. The Hb levels of all three groups were within the normal range, and the HbA1c levels of the B and S groups were significantly lower. The HbA1c levels of the B and S groups correlated negatively with Cu levels, and bone mineral density in the lumbar spine and in the femur correlated positively with the serum Cu levels. These results suggest that a deficient level of serum Cu might be related to a low HbA1c level and to a decrease in bone mineral density. Activity of some Brazilian copper bearing sulfides. The in vitro antimicrobial activity 82157476af
